Overview

Fiber Bragg Gratings face significant angular misalignment challenges in contemporary optical systems, primarily stemming from manufacturing tolerances, installation imprecision, and operational environmental factors. These wavelength-selective devices, formed by creating periodic refractive index modulations within optical fiber cores, have revolutionized. High-temperature-resistant fiber Bragg gratings (FBGs) are the main competitors to thermocouples as sensors in applications for high temperature environments defined as being in the 600–1200 °C temperature range. Due to their small size, capacity to be multiplexed into high density distributed. A novel approach to fibre Bragg grating spectra processing is proposed. The method is based on the use of nonlinear filtration and raising the spectrum value to the second power.
